Metering of cooling air in turbine blades.

A meter plate (40) formed from a depending member (42) extending from the root (18) of a turbine blade (16) to just short of the bottom (44) of the broach in a disk (14) in the live rim area is cast integrally with the blade (16) and serves with the broach to meter coolant flow from an on board injector (12) to internally of the blade. The member (42) can be machined to the size required to attain the desired amount of coolant flow for internal blade cooling.

FIG. 2

This invention relates to turbine blades for gas turbine engines and particularly to means for metering cooling air to internally cool the turbine blades.

As is well known in the gas turbine engine technology, the cooling of the turbine blades, particularly the first stage turbine, is extremely important not only to preserve the integrity of the blade structure but to also attain high engine performance by operating the turbine at optimum temperature levels. It is abundantly important in this environment to maximize the use of cooling air to avoid utilizing more air than is necessary so as to lessen the overall penalty that is attendant the use of engine air for purposes other than generating thrust or horsepower inasmuch as the gas turbine engine operates at higher efficiencies by operating the first stage turbine at higher temperatures and the trend for future engines is to increase turbine inlet temperatures so as to enhance engine efficiency and thereby reduce fuel consumption, the engine designer is faced with the problem of increasing turbine inlet temperature while at the same time attempting to reduce the amount of cooling air or at the very least to optimize its use.

As is well known, one method of optimizing the use of cooling air is to employ metering devices to restrict the flow entering into the roots of each of the blades. Typically, these flow restrictive or metering devices are comprised of an extra sheet metal component that is welded or brazed to the bottom of the blade. An example of a metering device that is bolted to the root of a stator blade is exemplified in U.S. Patent No. 3,706,508 granted to Moskowitz, et al on December 19, 1972 and entitled "Transpiration Cooled Turbine Blade with Metered Coolant Flow".

United Kingdom Patent Application No. 2 225 063 A published for Ulrich Radons on May 23, 1990 entitled "Turbine Cooling Arrangement" discloses an insert that is bonded to the blade base for flowing coolant into the rotor blades. Other patents that, while not necessarily teaching metering means, but relate to means for feeding coolant to the turbine rotor blades are U.S. Patent No. 4,767,261 granted to Godfrey et al on February 12, 1974 entitled "Cooled Vane" that utilizes a baffle plate internally of the vane; U.S. Patent No. 3,791,758 granted to Jenkinson on February 12, 1974 entitled "Cooling of Turbine Blades" that includes divergent walls for defining a diffuser for leading coolant to the root of the blades; and U.S. Patent No. 4,626,169 granted to Hsing et al on December 2, 1986 entitled "Seal Means for a Blade Attachment Slot of a Rotor Assembly" that provides a baffle that leads coolant to the rotor blades.

We have found that we can attain a more efficient use of cooling air and eliminate the extra component parts that were heretofore necessary for metering coolant with a consequential improvement in the castability of the blade, ease of fabrication and assembly by eliminating the brazing or welding operation, and

eliminate the need to inventory the component parts. While this results in lowering costs, it does have the disadvantage of slightly increasing weight.

However, there is a distinct advantage when utilizing this invention in cast film cooled, high efficiency turbine blade designs. The pressure of the tangential onboard injectors (known as TOBI) that serves to transmit the cooling air in the rotating machinery to the roots of the turbine blades is determined on the blade's outflow requirements and airfoil root leading edge stagnation pressure. This, typically, provides higher than required pressure air to the remaining portion of the blade. Therefore, to maintain acceptable flow levels for main body film cooling and trailing edge flow restricting features, (for example, crossover and film holes) these holes must be sized relatively small. By decreasing this pressure in these areas by use of the metering valve, these flow restricting features can be enlarged without increasing flow. The advantage of being able to increase the size of the holes enhances the castability of the blade and the film effectiveness.

In actual tests of blades employing this invention, the inventive meter plate increased the size of the trailing edge crossover holes to approximately 30% larger than heretofore known designs. In addition, the design made it possible to add additional film cooling holes in this configuration that was tested 3 extra film cooling holes were added in each of the rows of film cooling holes.

From a first broad aspect the invention provides a rotor comprising a blade having internal cooling passages, said blade being mounted by a root section in a recess on a rotor disk, said blade being cast with an integral projection which defines a coolant metering area within said recess.

From a second aspect the invention provides in combination, an internally air cooled turbine blade having a root section at one end and a turbine rotor disk for a gas turbine engine,

said blade being cast including a projection extending axially from said root section and being supported in a recess formed in the outer periphery of said rotor disk,

means for conducting cooling air into internal passages formed in said turbine blade through said recess,

said projection extending in said disk to define therein a metering plate to regulate the flow of cooling air from said recess into said passages, the length of said projection being modifiable after casting so as to select the amount of metering by said metering plate.

From a third broad aspect the invention provides a method of manufacturing a rotor having means for controlling flow of cooling air to the internal passages of an air cooled turbine blade for a gas turbine engine including the steps of:

casting the turbine blade including internal

cooling passages and a projection for fitting into a recess of a turbine rotor disk for defining a metering plate within said recess,

assembling the blade into the recess of said turbine rotor disk,

flowing cooling air into said recess to flow through a metering opening of said metering plate, and determining whether the flow is as desired, and if not,

disassembling said blade from said recess and machining said projection to adjust said metering plate so as to flow a desired amount of cooling air into said turbine blade.

From a yet further aspect, the invention provides a cast turbine blade having internal cooling passages and including an integrally cast projection extending axially from its root end for cooperation in use with a rotor disk to define a coolant metering area therewith.

A preferred embodiment of the invention will now be described, by way of example only, with reference to the accompanying drawings in which:

Fig. 1 is a partial sectional view of the turbine section of a gas turbine engine utilizing this invention;

Fig. 2 is an enlarged view of a turbine blade in elevation showing the details of this invention; and
Fig. 3 is a partial sectional view taken along lines 3-3 of Fig. 2.

While this invention is described herein in its preferred embodiment as being utilized on the first stage turbine of a gas turbine engine, as one skilled in this art will appreciate, this invention may be employed in other rotors. This invention in its preferred embodiment provides a combination of a meter plate and turbine blade defining with the live rim area of the disk the metering area, where the meter plate is cast integrally with the casting of the blade.

The invention can best be appreciated by referring to Fig. 1 which discloses the use of this invention in the first stage turbine section of a gas turbine engine (only partially shown). Inasmuch as the details of the engine are not necessary for an understanding of this invention, for the sake of convenience and simplicity only that portion of the engine necessary to describe this invention will be described. For more details of a gas turbine engine reference should be made to U.S. Patent No. 4,069,662 granted to Redinger, Jr., et al on January 24, 1978 entitled "Clearance Control for Gas Turbine Engine" or any of a number of engine models such as the F100, JT9D, PW2000 and PW4000, manufactured by the Pratt & Whitney Division of United Technologies Corporation, the present applicant.

Suffice it to say, that a portion of the air is bled from the compressor section (not shown) and is ultimately delivered to the turbine rotor generally indicated by reference numeral 10 through the TOBI 12 as depicted by arrows A.

The rotor comprises disk 14 suitably supports a plurality of circumferentially spaced turbine blades 16. The root 18 of each of the blades is attached to a recess or broach formed in the outer periphery or live rim area of the disk 14. In this design the broach is formed in a fir tree configuration which is a well known configuration for supporting the blades to the disk.

Rotor 10 is rotatably supported to the engine shaft and is disposed adjacent the first stator section 20 that is supported to the combustor generally indicated by reference numeral 22. As is well known, combustion air discharging from combustor 22 flows through the vanes of stator section 20 through blades 16, where work is extracted to power the compressor. As is apparent from the foregoing, the combustion gases that flow through the turbine blades are exceedingly hot necessitating cooling of the turbine rotor.

As shown in Fig. 2, blade 16 consists of a root 18, an airfoil section 26 having a tip section 28, leading edge 30 trailing edge 32 and a pressure side 34 and suction side (not shown) on the back of the pressure surface extending therebetween. Coolant is admitted into the live rim area 38 at the outer periphery of the disk and the root 18 and flows internally in the blade in a suitable manner and discharges therefrom through a plurality of film cooling holes 36 or shower head holes 37. As the detail of the cooling aspects of the blade is well known and described for example in U.S. Patent No. 4,820,123 granted to Kenneth B. Hall on April 11, 1989 for more details of a suitable turbine blade reference should be made to that patent.

As best shown in Figs 2 and 3, the meter plate generally indicated by reference numeral 40 consists of a depending member 42 integrally cast in the root 18 of blade 26 and extends in the live rim area 38 toward the upper surface 44 of disk 14. The bottom edge 46 extends just short of surface 44 and defines therewith the metering area 48. As noted in Fig 3, the cast metering plate depending member 42 extends between walls 50 and 52 defining the broach formed in disk 14.

It is apparent from the foregoing that the dimensions of the depending member 42 can be finalized after member 42 is cast. In this way, member 42 is cast oversized and is machined to the desired dimension in the finish machining of the blade. This will assure that the metering dimension is zeroed in to the desired area for achieving the desired pressure and flow of coolant for each blade. By being able to tailor the dimensions as described it is apparent that only the necessary amount of coolant needed to perform the desired cooling is utilized. Hence, each blade can be likewise tailored to assure that unnecessary coolant is not inadvertently used.

The method of adjusting the metering plate to meter the desired amount of cooling air to the internal

passages of the turbine blade is to assemble the blade with the oversized projection and flow test the assembly. Remove the blade and machine the oversized projection to obtain the desired metering area to meter the intended amount of cooling air. This is repeated until the correct amount is "zeroed in".

Another advantage of this integral design of the cast meter plate is that it does not add to the expense of casting the overall blade. Hence, not only is the invention inexpensive, it obviates all the problems associated with heretofore meter plates that are not integral with the blade.

From the above, it will be seen that at least in its preferred embodiments, the invention provides improved cooling means for the rotor blades of a gas turbine engine. It also provides an integrally cast metering plate extending from the root of the blade toward the live rim of the disk of the blade to define therewith a metering plate, and a method of "tailoring" the amount of cooling air metered by the metering plate.

The cast metering plate is characterized as being less costly than other metering plates, facilitates the assembly and disassembly of blade assemblies, and enhances cooling effectiveness.

Although this invention has been shown and described with respect to detailed embodiments thereof, it will be appreciated and understood by those skilled in the art that various changes in form and detail thereof may be made without departing from the scope of the claimed invention.

Claims

1. In combination, an internally air cooled turbine blade (16) having a root section (18) at one end and a turbine rotor disk (14) for a gas turbine engine,
 - said blade (16) being cast including a projection (42) extending axially from said root section (18) and being supported in a recess formed in the outer periphery of said rotor disk (14),
 - means for conducting cooling air into internal passages formed in said turbine blade (18) through said recess,
 - said projection (42) extending in said disk to define therein a metering plate (40) to regulate the flow of cooling air from said recess into said passages, the length of said projection being modifiable after casting so as to select the amount of metering by said metering plate (40).
2. The combination as claimed in claim 1 wherein said disk (14) includes a pair of opposing side walls (50,52) and a bottom wall (44) defining said recess, said projection (42) extending short of said bottom wall (44) and to the pair of side walls (50,52).
3. The combination as claimed in claim 1 or claim 2 wherein said recess is formed in a fir tree configuration.
4. The combination as claimed in any preceding claim including a tangential onboard injector (12) for conducting cooling air to said recess.
5. The combination as claimed in any preceding claim including a plurality of air cooled turbine blades (16) each having a root section (18) and cast with an axial projection (42) extending therefrom and supported in recesses formed in the outer periphery of said disk (14) and being circumferentially spaced, the spaces between each of said recesses defining side walls (50,52) and a bottom wall (44) of said recesses, said projection (42) of each of said air cooled turbine blades (18) extending in said recess short of the bottom wall (44) of each of said recesses, and the width of said projection (42) of each of said blades (18) being coextensive with the spacing between the opposing walls (50,52) of each of said recesses, and defining therewith enclosed chambers for receiving cooling air, and said each of said projections (42) together with said bottom wall (44) of said disk defining metering plates (40) for metering the flow in each of said chambers to said passages in each of said air cooled turbine blades.
6. A rotor comprising a blade (16) having internal cooling passages, said blade (16) being mounted by a root section (18) in a recess on a rotor disk (14), said blade (16) being cast with an integral projection (42) at its root section, which defines a coolant metering area (48) within said recess, the size or configuration of said projection being modifiable after casting to define a desired metering area.
7. A rotor as claimed in claim 6 wherein said projection (42) terminates short of a bottom wall (44) of a recess in said disk to define said metering area (48) between its lower edge and said bottom wall (44).
8. A gas turbine engine comprising a combination or a rotor as claimed in any preceding claim.
9. A method of manufacturing a rotor having means for controlling flow of cooling air to the internal passages of an air cooled turbine blade (16) for a gas turbine engine including the steps of:
 - casting the turbine blade (16) including internal cooling passages and a projection (42) for fitting into a recess of a turbine rotor disk (14) for defining a metering plate (40) within said recess,
 - assembling the blade (16) into the recess

of said turbine rotor disk (14),

flowing cooling air into said recess to flow through a metering opening (48) of said metering plate (40), and determining whether the flow is as desired, and if not,

5

disassembling said blade (16) from said recess and machining said projection (42) to adjust said metering plate (40) so as to flow a desired amount of cooling air into said turbine blade (16).

10

10. A cast turbine blade (16) having internal cooling passages and including an integrally cast projection extending axially from its root end for cooperation in use with a rotor disk to define a coolant metering area therewith.
